# Beam-Beam Background

- Most beam-beam background work has focused on  $e^+e^-$  pairs and high-pt hadrons.
- Muon pairs and low-pt hadrons are also produced and perhaps these events are important for forward tracking & calorimetry.

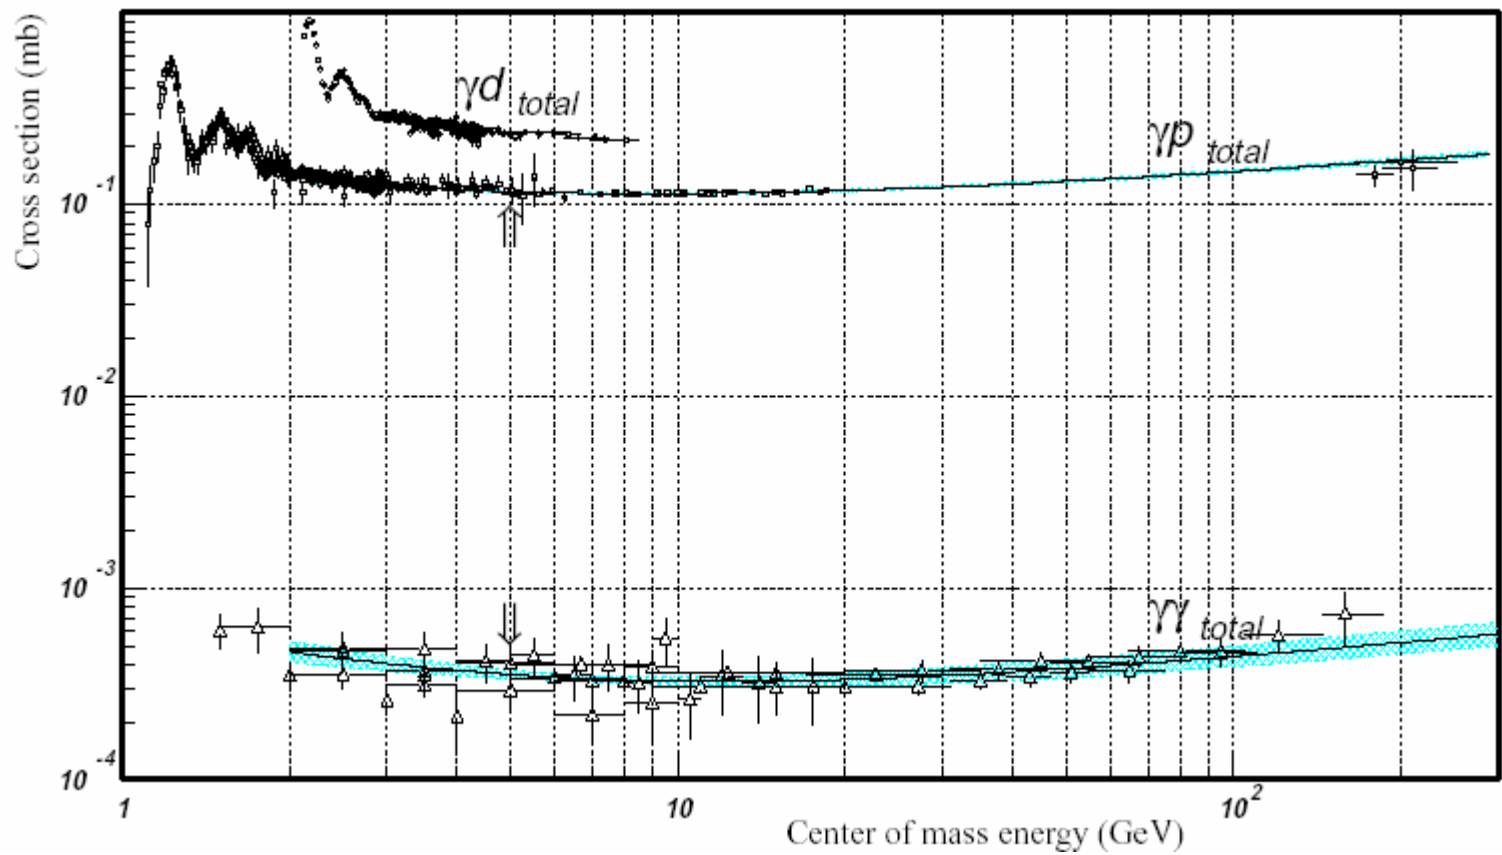

8600  $e^+e^-$  pairs / train strike detector

1.8 hadronic events / train with  $p_t > 2.2 \text{ GeV}$   
(TESLA TDR definition of hadronic bkgnd)  
79 GeV / train detected energy  
14.6 detected charged tracks / train

# Simulating Hadronic Events

- WHIZARD is used to simulate virtual photon flux & beamstrahlung flux (CIRCE).
- Total hadronic cross section given by a canonical formula for  $E_{cm} > 1.5$  GeV and by a constant 490 nb for  $0.3 < E_{cm} < 1.5$  GeV
- PYTHIA is used to model low and high-pt hadronic events for  $E_{cm} > 2$  GeV
- Isotropic production of 2, 3, or 4 pions for  $0.3 < E_{cm} < 2$  GeV.

154  $\mu^+ \mu^-$  pairs / train  
 56 GeV / train detected energy  
 24 detected charged tracks / train

56 hadronic events / train  
 no pt cut;  $E_{cm}$  down to  $\pi^+ \pi^-$  threshold  
 454 GeV / train detected energy  
 100 detected charged tracks / train

full train (56 events)  
454 GeV detected energy  
100 detected charged tracks

no timing

1/3 train (19 events)  
151 GeV detected energy  
33 detected charged tracks

21 nsec timing resolution  
(require  $3\sigma$  separation)

# Tracker Occupancies

# Summary

- Muon pairs and low-pt hadrons produced in the beam-beam interaction need to be considered along with  $e^+e^-$  pairs and high-pt hadrons.
- Muon pairs and hadrons create 124 detected charged tracks and 510 GeV detected energy per train. Tracker occupancies comparable to or greater than the occupancies from  $e^+e^-$  pairs.
- Further studies required to determine how well this background can be tagged and how much it will interfere with signal track finding/fitting and physics analyses.
