Outline

- Brief history
- Electron cloud
 - Effects
 - Production
 - Diagnostics
- Experimental observations
- Cures
- EC and electron beams
- Summary

Introduction

- A growing number of observations of electron cloud effects (ECEs) have been reported in positron and proton rings
- Low-energy, background electrons ubiquitous in high-intensity particle accelerators
- Amplification of electron cloud (EC) can occur under certain operating conditions, potentially giving rise to numerous effects that can seriously degrade accelerator performance
- EC observations and diagnostics have contributed to a better understanding of ECEs, in particular, details of beam-induced multipacting and cloud saturation effects
- Such experimental results can be used to provide realistic limits on key input parameters for modeling efforts and analytical calculations to improve prediction capability

Review talks at Accelerator Conferences: J.T. Rogers (PAC97), F. Ruggiero (EPAC98), K. Harkay (PAC99), F. Zimmermann (PAC01), G. Arduini (EPAC02) http://www.aps.anl.gov/asd/physics/ecloud/papers_top.html

ICFA Beam Dynamics Newsletter No. 31, Aug. 2003: special edition on High Luminosity e+e- Colliders http://wwwslap.cern.ch/icfa/

Workshops, past:

- Multibunch Instabilities Workshop, KEK, 1997 KEK Proc. 97-17
- Two-Stream ICFA Mini Workshop, Santa Fe, 2000 http://www.aps.anl.gov/conferences/icfa/two-stream.html
- Two-Stream Workshop, KEK, 2001 http://conference.kek.jp/two-stream/
- ECLOUD02, CERN, 2002 http://slap.cern.ch/collective/ecloud02/

Workshops, future (ICFA):

- Beam-Induced Pressure Rise, BNL, Dec. 9-12, 2003 (S.Y. Zhang, BNL)
- *ECLOUD04*, Napa, CA, Apr. 19-22, 2004 (M. Furman, LBNL)

Origins

Electron cloud effects (ECEs) were first observed ~30 yrs ago in small, medium-energy proton storage rings; described as: Vacuum pressure bump instability, e-p instability, or beam-induced multipacting:

- **BINP Proton Storage Ring** [G. Budker, G. Dimov, and V. Dudnikov, Sov. Atom. E. 22, 5 (1967); see also review by V. Dudnikov, PAC2001, 1892 (2001)]
- CERN Intersecting Storage Ring (ISR) [Hereward, Keil, Zotter (1971)]
- Proton Storage Ring (PSR) [D. Neuffer et al. (1988, 1992)]

First observation in a positron ring ca. 1995: Transverse coupled-bunch instability in e+ ring only and not in e- ring:

- KEK Photon Factory (PF) [M. Izawa, Y. Sato, T. Toyomasu, PRL 74, 5044 (1995) and K. Ohmi, PRL 75, 1526 (1995)]
- IHEP Beijing e+/e- collider (BEPC): experiments repeated and PF results verified [Z.Y. Guo et al., PAC1997, 1566 (1997)]

See article by F. Zimmermann, ICFA BD Newsletter No. 31, Aug. 2003

Origins (cont.)

SLAC PEP-II and KEKB B-factories both under development; became concerned about ECEs:

Codes developed to model EC generation and instabilities:

- PEI, KEK (K. Ohmi)
- POSINST, LBNL (M. Furman et al.)
- ECLOUD, CERN/SLAC (F. Zimmermann et al.)
- PEP-II: Decision made to coat chambers with low-δ TiN
- KEKB: Solenoid winding-machine designed, later entire chamber wound by hand
- Calculated predictions of a BIM resonance in LHC, also under development, resulted in a crash program at CERN to study ECEs.

We were asked why we don't observe ECEs in the APS with Al chambers (high δ) and positron beams? Started experimental program in 1997-8 first with e+ beam, then since 1998 with e- beam.

Outline

- Brief history
- Electron cloud
 - Effects
 - Production
 - Diagnostics
- Experimental observations
- Cures
- EC and electron beams
- Summary

Electron cloud effects

- Vacuum and beam lifetime degradation through electronstimulated gas desorption
- Collective instabilities
 - Transverse coupled-bunch instability (electron cloud "wake")
 - Single-bunch instability; emittance blow-up ("head-tail" instability; luminosity degradation)
 - e-p instability (coupled oscillations)
- Electrons trapped in spurious magnetic fields, e.g., distributed ion pump leakage field (CESR)
- Cloud-induced noise in beam diagnostics (e.g., wire scanners, ion profile monitors, etc.)
- Enhancement of other effects, i.e., beam-beam (?)

Electron cloud production

Primary

- Photoelectrons
- Ionization of residual gas
- Beam loss on chamber walls

Secondary

- Secondary
 emission
 (δ is secondary
 electron yield
 coefficient)
- $-\delta_0 \sim 0.5$

Figure courtesy of R. Kirby

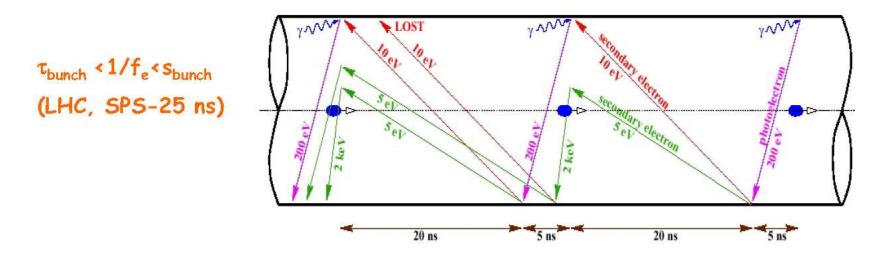

Electron cloud production (cont.)

Photoelectrons can dominate the cloud if there is no antechamber

Beam-induced multipacting

Schematic courtesy of G. Arduini

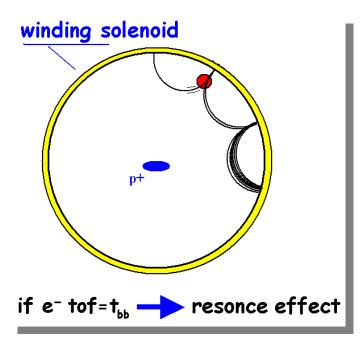

- δ > 1 required for amplification
- Energy distribution of SE leads to more general BIM condition (first suggested by S. Heifets and M. Furman)

Diagnostics

Standard beam diagnostics

- Vacuum pressure
- Bunch-by-bunch tune
- Beam size

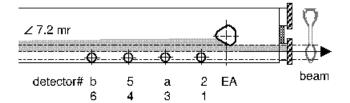

Dedicated diagnostics

EC on wall: Retarding field analyzer (RFA)

mounting on APS Al chamber behind vacuum penetration (42 x 21 mm half-dim.)

mounting on 5-m-long APS chamber, top view, showing radiation fan from downstream bending magnet

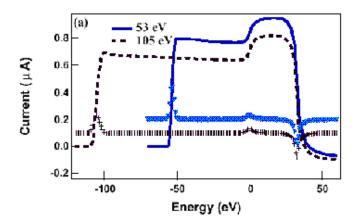

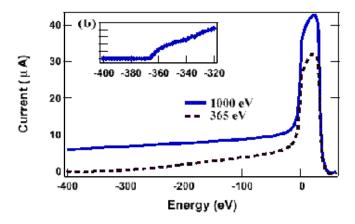

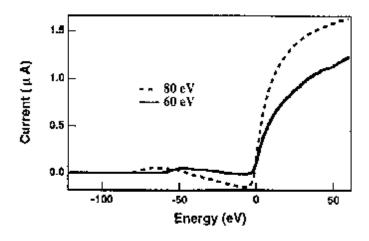

Advantage of RFA to biased electrode

RFA, normal (top) vs. angular (bottom) incidence (collector biased +45 V)

Biased BPM, normal incidence

EC in chamber is not shielded from biased grid or collector

Varying electrode bias voltage

- Changes incident electron energy
- Changes collection length

Difficult to deduce true wall flux

Outline

- Brief history
- Electron cloud
 - Effects
 - Production
 - Diagnostics
- Experimental observations
- Cures
- EC and electron beams
- Summary

Experimental observations

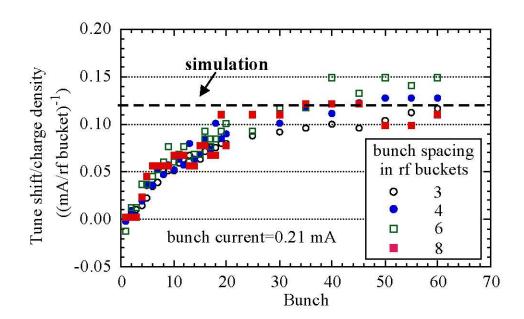

- Cloud build-up and saturation
- Vacuum pressure rise
- Surface conditioning
- Z-dependence
- Secondary electron (SE)- vs. photoelectron (PE)-dependence
- Proton rings
 - CERN SPS with LHC-type beams
 - Proton Storage Ring (PSR)
- Electron decay time
- EC-induced collective effects

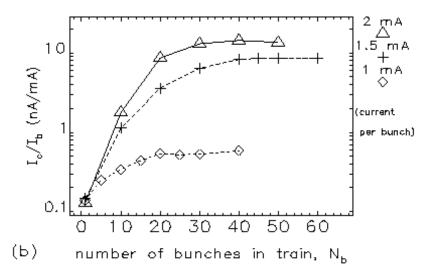

Cloud build-up and saturation

KEKB: EC saturates after 20-30 bunches per tune shift ($4\lambda_{rf}$ bunch spacing)

Courtesy of H. Fukuma, Proc. ECLOUD'02, CERN Report No. CERN-2002-001(2002)

APS: EC saturates after 20-30 bunches (middle of straight); level varies nonlinearly with bunch current ($7\lambda_{rf}$ bunch spacing)

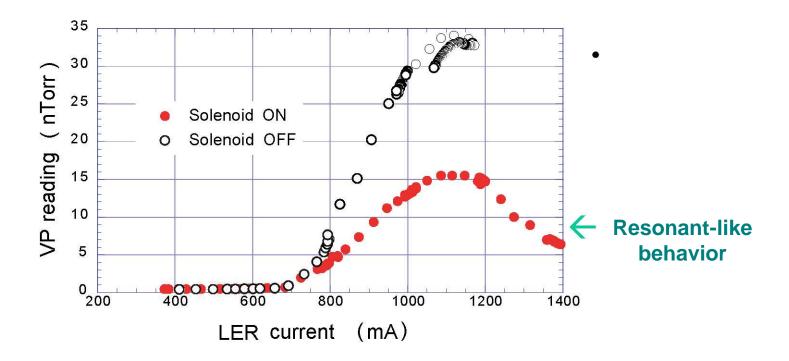

Office of Science U.S. Department of Energy

Vacuum pressure rise

PEP-II: courtesy of A. Kulikov et al., PAC 2001, 1903 (2001)

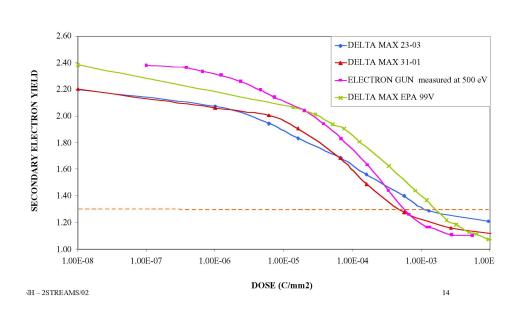

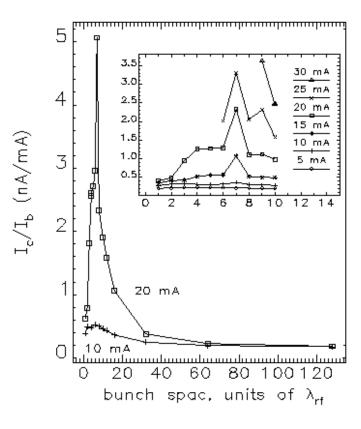

Pressure rise also observed in KEKB, SPS, APS (and RHIC?)

Surface conditioning

Courtesy of N. Hilleret, Proc. Two-stream Instability Workshop, KEK, Japan (2001)

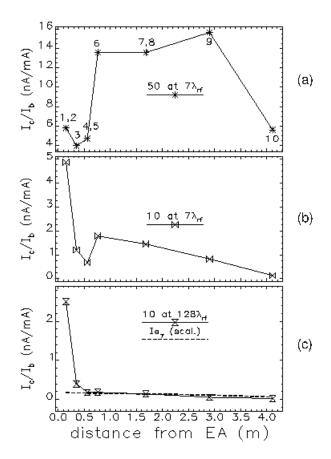

Wall flux at APS reduced 2x after 60 Ah of surface conditioning, equivalent to 10⁻³ C/mm², consistent with CERN data (Cu) (APS chamber AI)

Z-dependence

APS: Measured RFAs as function of bunch number, spacing, and distance from photon absorber (2 mA/bunch).

KEKB: EC with space charge in solenoid modeled with 3D PIC code

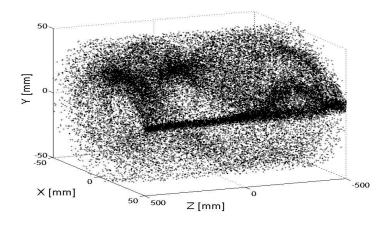

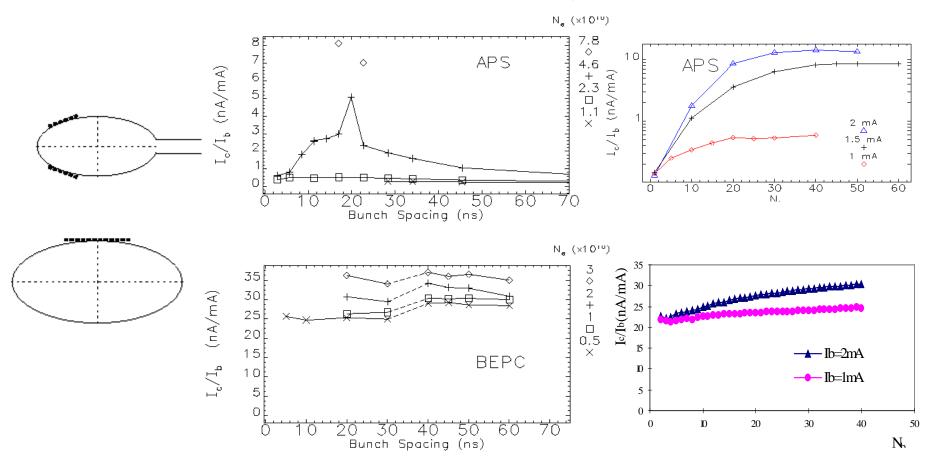

Figure courtesy of L. Wang, H. Fukuma, K. Ohmi, E. Perevedentsev, APAC 2001, 466 (2001)

SE- vs. PE-dominated

No BIM and nearly linear EC density observed in BEPC e+ ring

BEPC data courtesy of Z. Guo et al.

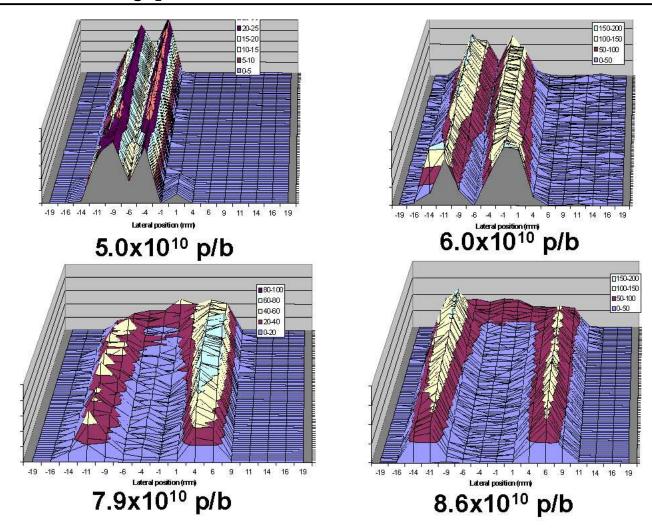

CERN SPS – LHC-type beams

Measured EC distribution in special dipole chamber fitted with strip detectors

Qualitatively confirmed simulation showing two stripes

Figures courtesy of J.M. Jiminez, G. Arduini, et al., Proc. ECLOUD'02, CERN Report No. CERN-2002-001 (2002)

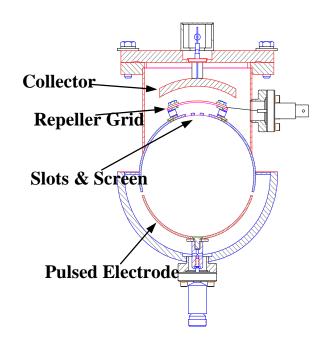

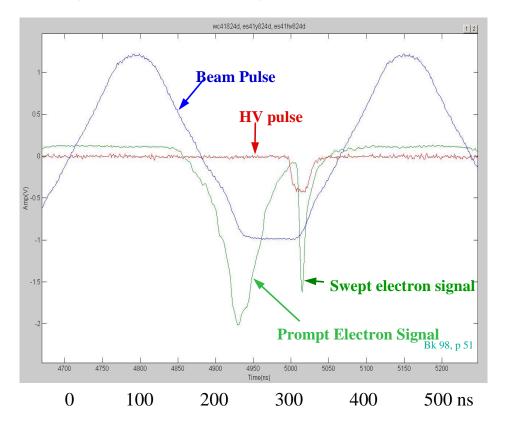

Proton Storage Ring (PSR)

LANL Electron Sweeper (~500 V pulse) 80MHz fast electronics added

Prompt electron signal due to trailing-edge multipactor; swept electrons survive gap (7.7 μC/pulse, bunch length = 280 ns; repeller –25 V)

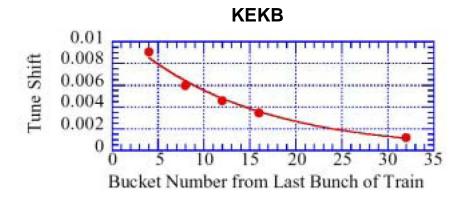

Courtesy R. Macek A. Browman, T. Wang

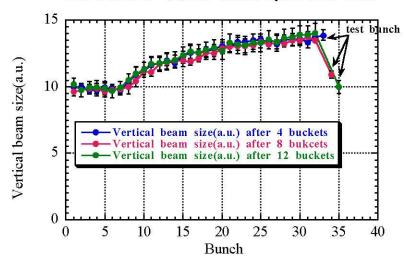

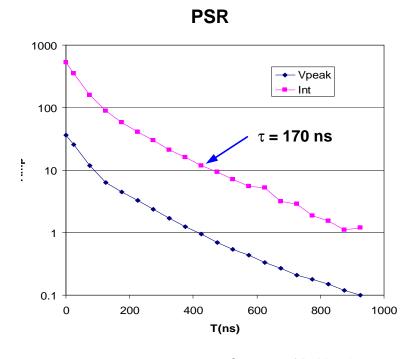

Decay time of electron cloud

4 buckets spacing, 32 bunches Test bunch at 4,8,12th bucket apart from train

Courtesy of R. Macek

KEKB: 25-30 ns vs.

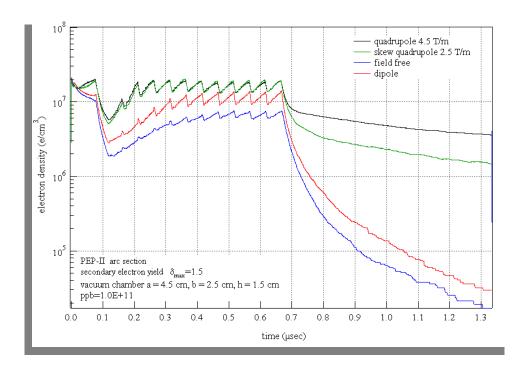

PSR: 170 ns decay time

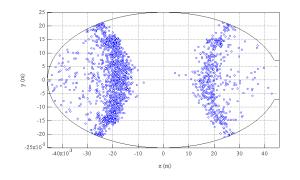

Courtesy of H. Fukuma, Proc. ECLOUD'02, CERN Report No. CERN-2002-001 (2002)

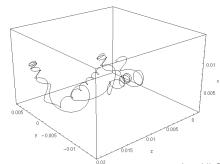

Electron trapping mechanism in quadrupole

Particular attention at quadrupoles where electron trapping mechanism is possible (magnetic mirror, see also Jackson .. !)

(ex: NLC MDR quad)

PEP-II arc simulations + skew quadrupole. Decay time after long gap. By-2 bucket spacing, 10 out of 12 bunches with mini-gaps, 10¹¹ ppb. Arc quadrupole gradient 4.5 T/m and skew quarupole 2.5 T/m. Elliptic vacuum chamber 4.5 x 2.5 cm with antechamber.

 $\left| \frac{v_{\parallel,0}}{v_{\perp,0}} \right| = \left(\frac{B_{pipe}}{B_0} - 1 \right)^{1/2}$

Contributions to understanding ECEs come from a growing community

Modeling efforts and benchmarking continue to be refined as more physics added:

- Accelerator physics
- Vacuum, surface chemistry
- Plasma wakefield accelerators
- Heavy ion fusion
- Photocathode materials science, electron guns
 - Modeling electron dynamics in MV fields requires accurate EC distribution

Electron cloud and other effects

K. Harkay, ANL

- Combined phenomena (enhancement) of beam-beam and electron cloud (E. Perevedentsev, K. Ohmi, A. Chao, 2002)
- Combined effect of EC and intensity-dependent geometric wakes
- Microwaves as diagnostic or suppressor of cloud (S. Heifets, A. Chao, F. Caspers, F.-J. Decker)

Outline

- Brief history
- Electron cloud
 - Effects
 - Production
 - Diagnostics
- Experimental observations
- Cures
- EC and electron beams
- Summary

Cures

- Avoid BIM resonance through choice of bunch spacing, bunch current, and chamber height; include SE emission energy in analysis
- Minimize photoelectron yield through chamber geometry (antechamber, normal incidence)
- Consider passive cures implemented in existing machines:
 - Surface conditioning or surface coatings to minimize δ ; e.g. TiN, TiZrV NEG
 - Solenoidal B-field to keep SEs generated at wall away from beam;
 this works in machines dominated by ECs in the straights (i.e., not in the dipoles)
- Implement fast beam feedback
- Continue to refine models and continue to develop and implement electron cloud diagnostics, especially in B-fields

Electron beams - a side note

J. Galayda (ca. 1997) suggested EC can impact electron beams

BIM-like bunch-spacing dependence of EC observed for electron beam, but effect 10x smaller than for positrons, and avg. EC energy 10x smaller (10 eV vs. 100 eV)

Search for User bunch pattern with electron beam at APS:

- 1. Trains of 4 bunches (11.4 ns) separated by $2\lambda_{rf}$ (5.7 ns)
- 2. Trains of 4 bunches (11.4 ns) separated by $12\lambda_{rf}$ (34 ns)

Pattern 1 gave twice vacuum pressure, half the beam lifetime, and RFA signals 3-5x higher than pattern 2.

Repeated one year later, effect disappeared (surface conditioning?)

Calculations (*POSINST*) of power deposition on walls for superconducting ID give up to 1 W/m *with electron beam* (Al, 4x less with TiN). Code benchmarked for both e+ and e- beams.

Summary

- Electron cloud effects are increasingly important phenomena in high luminosity, high brightness, or high intensity machines
 - Colliders, Storage rings, Damping rings, Heavy ion beams
- EC generation modeling benchmarked against *in situ* data: δ , δ_0 , photon reflectivity, and SE energy distributions important
- Surface conditioning and use of solenoidal fields in field-free regions are successful cures: will they be enough?
- Work to be done in areas not well understood, for example:
 - Effect of 3D density variation in cloud on instability thresholds
 - Differences in cloud lifetime
 - Combined effects of EC and other dynamics, e.g. beam-beam
- New effects? Longitudinal? ECE in electron beams?
